# API Rest Server SAP -> NIS

The goal of this API is to provide information to NIS (Next IMPROVE System) about the work order related to the product units stocked on each of the entry position of a generic machine (in this case laser and bending machines).

Thanks to the communication between SAP and the AGV system, SAP knows exactly the time and the entry position where each product unit is stocked by the AGV (frequency diagram below).
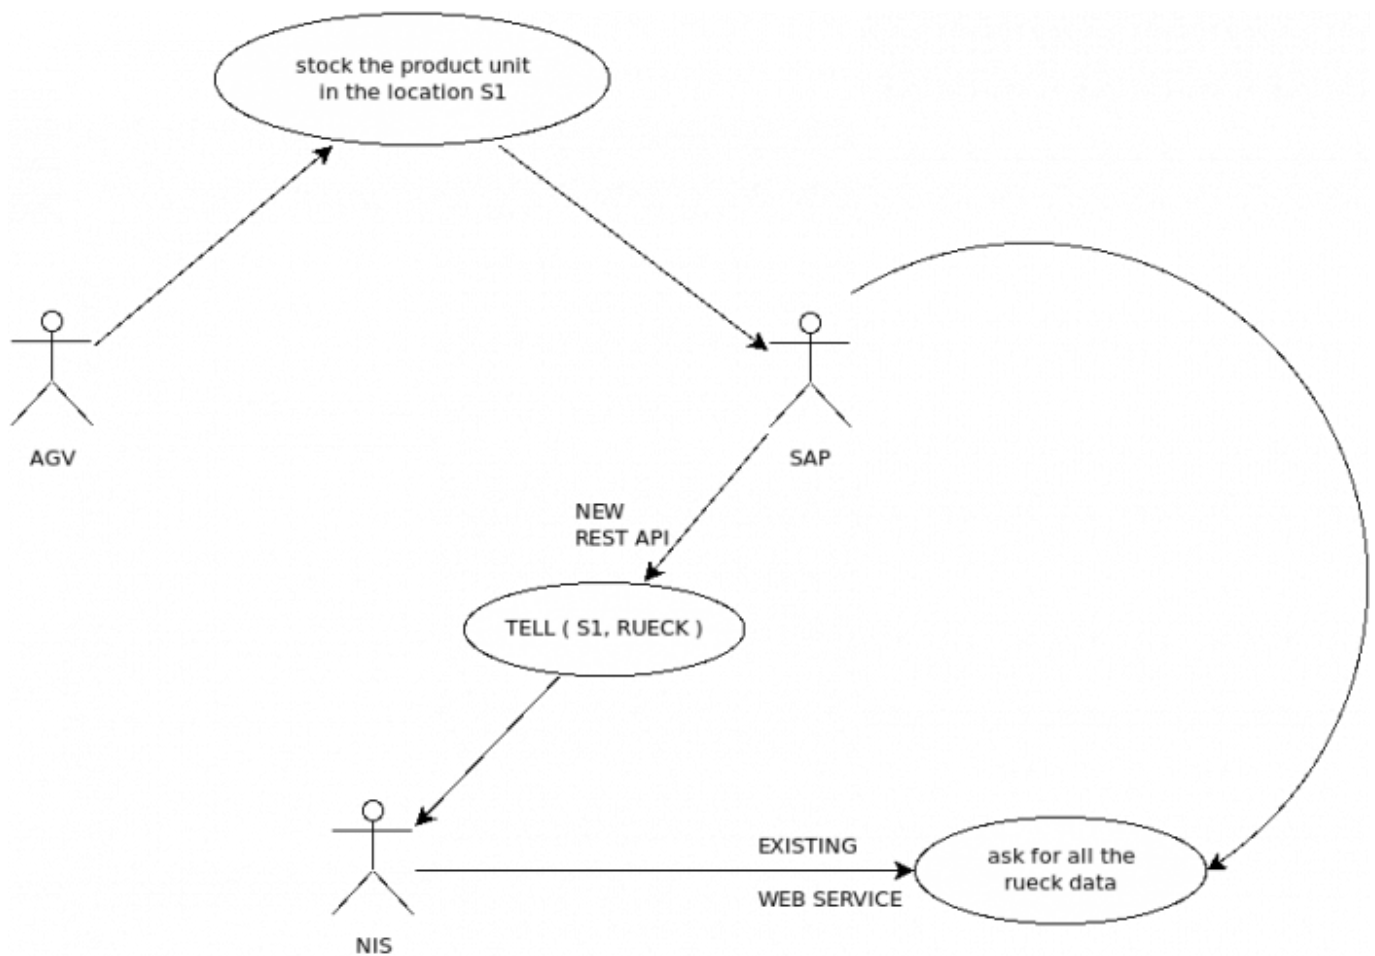

Once SAP receives the message that defines the right completition of the AGV mission (stocking of a specific product unit in a specific entry location of a specific machine) it can send to NIS the related rueck.

next

PLC (Starmatik)	SIGAT (ASTI)	SAP	NEXT

request to pick an empty pallet
and to deliver a full one to S1

remove the empty pallet and request a
transfer order for the full pallet

send transfer order from
semifinished storage to S1

AGV delivers the full pallet and informs the
machine on the material (Product Code,
Order Number, Quantity)

.../SAPOrderStatus.Phase = 10

SIGAT informs SAP that the
order has been executed

send material and
production order data

SAP informs NEXT on the material that has
been transported to S1 and on the
production order associated to that material.

AGV has left the station
OperationCompleted = 1

request new job to NEXT
for the material in S1

add a new job to machine worklist

NEXT passes to the machine all the
information necessary to process the material
in S1

production feedback

The machine works the material and gives
feedback to NEXT for every part completed.

SAP will send to NIS the following information:

1. **machine entry position identifier**: this is a shared identifier that is unique inside all the machines entry positions
2. **rueck**: is the rueck related to the product unit stocket in the specific machine entry position

After that, NIS will download all the required information using the existing web service protocol. The following use case diagram describes the scenario.

NIS will provide a REST server API with the following properties:

- IP:PORT ⇒ 255.255.255.255:9999 (to be defined, 10.100.145.19:5599 on the test server)
- Protocol HTTP
- Method POST

```
http://255.255.255.255:98999/iaf/tell/rueckmng
(http://10.100.145.19:5599/iaf/tell/rueckmng on the test server)
```

- BODY as json text:

```
{"request":"pustock","p1":{"entrypos":"XXXXXX","rueck":"99999999"}}
```

In the following there is the description of the json fields

- request: is a static string value containing "pustock"
- p1: is the data object, where
  - entrypos: is the unique identifier of the machine entry position
  - rueck: is the related rueck

The Rest server will answer through the following json object:

- {"rv":"1"} if the operation is done with success
- {"rv":"0"} if the operation is done without success

In the following an example using the **curl** command:

```
curl --request POST 'http://10.100.145.19:5599/iaf/tell/rueckmng' --header
'Content-Type: application/json' --data-raw
'{"request":"pustock","p1":{"entrypos":"XXXXXXX","rueck":"99999999"}}'
```
